

**REMARKS**

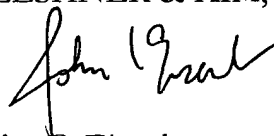

Claims 1-14, and 17-46 are pending. Claims 1-14, 17-28, 30-32 and 34-45 have been amended. Claims 15-16 are canceled and claim 46 is added. Prompt examination and allowance in due course are respectfully solicited.

**CONCLUSION**

Should the Examiner have any questions regarding the above-identified application, the Examiner is invited to contact the undersigned attorney at the telephone number listed below.

To the extent necessary, a petition for an extension of time under 37 C.F.R. 1.136 is hereby made. Please charge any shortage in fees due in connection with the filing of this, concurrent and future replies, including extension of time fees, to Deposit Account 16-0607 and please credit any excess fees to such deposit account.

Respectfully submitted,

Please replace the entire Specification with the attached substitute Specification. A hand markup of the original specification is also enclosed for the Examiner's information.

## REFRIGERATOR

Technical Field

The present invention relates to a refrigerator, and more particularly, to a refrigerant  
 5 circulating device of the refrigerator.

Background Art

In general, a refrigerator is an apparatus <sup>for storing</sup> ~~for taking storage~~ of foods <sup>at</sup> ~~freshly by keeping~~ a  
 low temperature in a freezing chamber and a refrigerating chamber. To maintain the low  
 10 temperature in the freezing chamber and the refrigerating chamber, the refrigerator  
 generates ~~a~~ cool air by using a freezing cycle of compressing-condensing-expanding-  
 evaporating. Then, the generated cool air is provided to and circulated in the freezing  
 chamber and the refrigerating chamber ~~by using a supplying device, wherein~~ The  
 supplying device is comprised of a passage <sup>for</sup> ~~of~~ supplying the cool air from the freezing  
 15 cycle to the refrigerating chamber and the freezing chamber, <sup>or duct</sup> ~~and~~ openings of discharging <sup>e</sup>  
 the cool air to the refrigerating chamber and the freezing chamber. <sup>in the walls of the refrigerating + freezing chamber</sup>  
<sup>A</sup> Typically, the openings are  
 However, each opening is relatively smaller as compared with a volume in each of the  
 freezing chamber and the refrigerating chamber, <sup>As a result,</sup> ~~so that~~ it is impossible to discharge a  
 large amount of cool air <sup>into</sup> ~~to~~ the refrigerating chamber and the freezing chamber in a short  
 20 time. <sup>Also, because</sup> ~~Especially, since~~ the discharged cool air has a relatively high flowing <sup>rate</sup> ~~speed~~, the

discharged cool air flows <sup>in</sup> to a specific direction <sup>out of</sup> from the openings, and more particularly, a straightforward direction. As a result, the cool air is not uniformly diffused in the entire refrigerating chamber and the entire freezing chamber.

## 5 Disclosure of Invention

An object of the present invention, designed for solving the foregoing problems, is to provide a refrigerator for uniformly providing a cool air to the inside.

~~The object of the present invention can be achieved by providing a refrigerator, the~~ <sup>A refrigerator embodying</sup>

~~refrigerator~~ includes a body; a refrigerating chamber and a freezing chamber provided in

10 ~~the body, for taking storage of foods; a cool air-generating device provided in the body,~~

~~for generating a cool air; a cool air-supplying device including at least one opening for~~

~~discharging the cool air, and for circulating the cool air through the freezing chamber,~~ <sup>into</sup> ~~the~~ <sup>and</sup>

~~refrigerating chamber, and the cool air-generating device; and a separator provided~~

15 ~~adjacent to the opening, for uniformly diffusing the cool air in the freezing chamber and~~  
~~the refrigerating chamber,~~ <sup>Streams.</sup> ~~by separating the cool air into at least two passages.~~

~~At this time, The separator is provided to block the discharged cool air.~~ <sup>partially</sup> ~~Also, The~~  
~~separator is extended in perpendicular to a flowing direction of the cool air.~~ <sup>may</sup> ~~being discharged from~~  
<sup>the opening</sup>

~~The separator oscillates the discharged cool air. In more detail, the separator generates~~

~~at least two vortices in opposite, wherein The vortices have size and intensity being~~ <sup>may be configured to</sup> <sup>may</sup> <sup>a</sup> <sup>an</sup>  
<sup>in the discharged cool air that rotate in opposite directions.</sup>

20 ~~different and continuously changed.~~ <sup>that</sup> <sup>change</sup> <sup>that are</sup> Also, the separator is configured to allow the

separated <sup>flows</sup> passages of the cool air to collide with each other before <sup>they are</sup> discharging <sup>ed</sup> the cool

air. The separated <sup>flows</sup> passages of the cool air collide with each other in a straight line, and

~~the separated passages of the cool air collide with each other~~ at a predetermined angle.

~~At this time,~~ <sup>may be as</sup> the separator ~~is~~ formed of a flat member. <sup>Also</sup> ~~In the meantime,~~ the separator

5 ~~may be formed of~~ a round shape <sup>that</sup> being protruded <sup>S</sup> ~~in~~ opposite to a flowing direction of the <sup>have</sup>

cool air. The separator may be formed of an angularly bent shape <sup>that</sup> being protruded <sup>S</sup> ~~in~~ <sup>also</sup>

opposite to a flowing direction of the cool air. Also, the separator may be formed of an

oval shape <sup>wherein</sup> ~~to have~~ both sides <sup>are</sup> being round <sup>in</sup> for the forward and opposite directions of the

cool air. A plurality of protrusions or dimples may be formed on the surface of the

10 separator.

Two opposite passages are formed between the separator and the opening, and the <sup>flows of</sup> separated cool air <sup>pass</sup> flows along the two opposite passages. <sup>In some embodiments,</sup> ~~Also,~~ the opening is positioned

adjacent to a crossing point ~~of meeting the separated passages~~ of the cool air. In addition,

<sup>where the separated flows</sup> an interval between the separator and the opening <sup>come back together</sup> is equivalent to (or smaller than) a <sup>may be</sup>

15 width of the opening. Preferably, an interval between the separator and the opening is

about 0.5 times of a width of the opening. Also, preferably, a width of the separator is

equivalent to a width of the opening.

The opening is configured to discharge the generated cool air to the freezing chamber and the refrigerating chamber. Preferably, the opening is configured to discharge the

20 generated cool air to the freezing chamber and the refrigerating chamber at least two

the opening discharges the cool air circulated in the freezing chamber and the

refrigerating chamber to an evaporator of the cool air-generating device. Preferably, the

cool air-supplying device further includes an auxiliary duct extended adjacent to the

evaporator of the cool air-generating device, for directly discharging the cool air

circulated in the freezing chamber and the refrigerating chamber to the evaporator. The

separator is positioned adjacent to an opening of the auxiliary duct.

The cool air-supplying device may include at least one duct of circulating the cool air

from the cool air-supplying device to the opening. In this case, the duct may be

expanded towards the inside of the refrigerating chamber and/or the freezing chamber.

15 Preferably, the duct has an expanded portion adjacent to the separator. Also, a width of

the expanded portion is about 2 to 2.5 times of a width of the corresponding duct, and a

height of the expanded portion is about 1 to 1.2 times of a width of the corresponding

duct. The duct is gradually expanded. More preferably, a sidewall of the expanded

portion is inclined at a predetermined angle to a sidewall of the duct.

that deliver cool air to the refrigerating and freezing chamber

<sup>(A)</sup> <sup>embodying the invention</sup>  
~~In the meantime, the~~ refrigerator may have a plurality of openings and separators,

wherein the separators are respectively positioned adjacent to the openings. In this case,  
 the adjacent separators oscillate the discharged cool air <sup>in</sup> ~~at~~ <sup>5</sup> perpendicular direction.

Preferably, the adjacent separators are configured to separate the discharged cool air ~~at~~ <sup>in</sup>

5 different directions. Also, the separator <sup>(S)</sup> <sup>may</sup> further includes <sup>that</sup> one pair of supports extended  
 from the opposite sides of the separator near to the opening, ~~for supporting the separator,~~  
~~wherein each in one pair of supports from the adjacent separators supports the opposite~~  
~~side.~~

Accordingly, ~~the cool air is uniformly diffused in the freezing chamber, the refrigerating~~  
 10 ~~chamber, and the evaporator.~~

### Brief Description of Drawings

The accompanying drawings, which are included to provide a further understanding of  
 the invention, illustrate embodiment(s) of the invention and together with the description  
 15 serve to explain the principle of the invention. In the drawings:

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Best Mode for Carrying Out the Invention

Reference will now be made in detail to the preferred embodiments of the present invention, examples of which are illustrated in the accompanying drawings. ~~In describing the embodiments, parts the same with the related art fuel cell will be given the same names and reference symbols, and detailed description of which will be omitted.~~

Hereinafter, ~~a refrigerator according to the present invention will be described with reference to the accompanying drawings.~~

FIG. 1 is a front view of a refrigerator according to the present invention. FIG. 2 is a front section <sup>al</sup> view of a refrigerator according to <sup>a</sup> the first embodiment of the present invention. FIG. 3 is a cross section <sup>al</sup> view of a refrigerator according to the first embodiment of the present invention.

As shown in the drawings, the refrigerator according to the first embodiment of the present invention <sup>include</sup> is ~~largely provided with~~ a body 10, a freezing chamber 30, a refrigerating chamber 40, a cool air-generating device, and a cool air-supplying device, wherein the freezing chamber 30 and the refrigerating chamber 40 are provided inside the body 10.

First, <sup>holds frozen</sup> the freezing chamber 30 ~~freezes~~ foods, and the refrigerating chamber 40 keeps foods ~~in~~ cold, so that foods are stored freshly. The freezing chamber 30 and the refrigerating chamber 40 are formed <sup>by</sup> ~~in a method of~~ dividing an inner space of the body 10 ~~by~~ a barrier 20.

<sup>with</sup>

In the refrigerator according to the first embodiment of the present invention, the freezing chamber 30 and the refrigerating chamber 40 are positioned side by side. Alternatively, the freezing chamber 30 and the refrigerating chamber 40 may be positioned up and down.

5 The cool air-generating device is configured to generate ~~a~~ cool air <sup>which is</sup> discharged <sup>into</sup> to the freezing chamber 30 and the refrigerating chamber 40. ~~Also,~~ <sup>the</sup> cool air-generating device is provided with a compressor, a condenser, an expanding valve, and an evaporator 71.

<sup>into</sup>  
Herein, ~~the~~ compressor makes a low temperature/low pressure gaseous refrigerant ~~to~~ a  
10 high temperature/high pressure gaseous refrigerant, and the condenser condenses the gaseous refrigerant provided from the compressor. Also, the expanding valve lowers the pressure of the refrigerant provided from the condenser. Then, the evaporator 71 evaporates the refrigerant passing through the expanding valve in state of the low pressure, to absorb heat ~~from~~ <sup>changed</sup> from the surrounding air. Thus, the surrounding air is <sup>cooled</sup>  
15 ~~to the cool air.~~

As shown in FIG. 3, the compressor and the condenser (not shown) are provided in a machine room 12 at a lower portion of the body 10. Also, the evaporator 71 is provided in an additional room adjacent to the freezing chamber 30 and the refrigerating chamber 40. In addition, a fan or a blower 72 is also provided in the additional room ~~for being~~

adjacent to the evaporator 71 so that the air is continuously circulated inside the refrigerator.

The cool air-supplying device discharges ~~the~~ <sup>by</sup> cool air generated in the cool air-generating device to the freezing chamber 30 and the refrigerating chamber 40. Also, the cool air-supplying device <sup>recirculates</sup> ~~provides~~ the discharged cool air <sup>from the refrigerating and freezing chambers back</sup> to the evaporator 71. ~~for being cool~~ <sup>again</sup>. That is, the cool air-supplying device continuously provides and circulates the cool air through the freezing chamber 30 and the refrigerating chamber 40, and ~~more~~ <sup>and then back to</sup> ~~particularly, through~~ the evaporator 71, whereby the freezing chamber 30 and the refrigerating chamber 40 are respectively maintained below a specific temperature. ~~This~~ <sup>The</sup> cool air-supplying device may be provided with a first supplying part for the refrigerating chamber 40, and a second supplying part for the freezing chamber 30.

Referring to FIG. 2, the first supplying part is comprised of a first duct 50 for guiding the cool air to the refrigerating chamber 40, and first and second openings 51 and 52 for discharging the guided cool air to the refrigerating chamber 40.

As shown in FIG. 1 and FIG. 3, the first duct 50 is in communication with the room for the evaporator 71 by a first middle opening 21 provided in the barrier 20. Accordingly, the cool air is directly provided to the first duct 50 through the first middle opening 21.

The first and second openings 51 and 52 are positioned at the upper and lateral sides of the refrigerating chamber 40 for smoothly supplying the cool air to the refrigerating chamber 40. If necessary, the plurality of first and second openings 51 and 52 may be

provided to the refrigerating chamber 40. Also, a second middle opening 22 is provided at a lower side of the barrier 20, wherein the second middle opening 22 is in communication with both the refrigerating chamber 40 and the freezing chamber 30. Thus, the cool air of the refrigerating chamber 40 is discharged to the freezing chamber 30 through the second middle opening 22.

The second supplying part is provided with a second duct 60 for guiding the cool air to the freezing chamber 30 and the evaporator 71, and <sup>↑</sup>at least one or more third and fourth openings 61 and 62 being in communication with the second duct 60.

As shown in FIG. 3, the second duct 60 is provided between the freezing chamber 30 and the evaporator 71. The second duct 60 is in communication with the evaporator 71 by a third middle opening 63, and the second duct 60 receives the cool air from the evaporator 71 by the fan 72. The third opening 61 discharges the cool air of the second duct 60 to the freezing chamber 30. The fourth opening 62 discharges the cool air of the freezing chamber 30 to the evaporator 71 so as to cool the air.

In this refrigerator according to the present invention, the air is cooled during passing through the evaporator 71 by the fan 72. Subsequently, the cool air is provided to the first duct 50 and the second duct 60 through the first middle opening 21 and the <sup>third</sup> ~~second~~ middle opening <sup>63</sup> ~~22~~. After that, the cool air is discharged to the refrigerating chamber 40 through the first opening 51 and the second opening 52, and is discharged to the freezing chamber 30 through the third opening 61.

However, as explained above, <sup>in related art refrigerators</sup> the cool air doesn't uniformly reach the freezing chamber 30 and the refrigerating chamber 40 due to the small-sized first, second, and third openings 51, 52, 61 and <sup>the</sup> circulation speed/direction. Thus, in case of the refrigerator <sup>of the cool air</sup> according to the first embodiment of the present invention, as shown in FIG. 2 to FIG. 4, separators 100 are provided <sup>in</sup> to the openings 51, 52, 61 for discharging the generated cool air to the freezing chamber 30 and the refrigerating chamber 40.

As shown in FIG. 4, each of the separators 100 separates the cool air <sup>into</sup> at least two <sup>separate flows</sup> passages before discharging the cool air. That is, the separators 100 are provided adjacent to the openings 51, 52, 61, and more particularly, not inside the freezing chamber 30 and the refrigerating chamber 40 but inside the ducts 50, 60. ~~According to~~ <sup>The separators 100 serve to</sup> the separation on passage of the cool air, ~~it is possible to~~ decrease the circulation speed of the cool air. ~~Thus, it is very useful to diffuse the cool air in the freezing chamber and the refrigerating chamber.~~ <sup>and</sup> <sup>more uniformly throughout</sup>

Also, ~~the separators 100 are provided to block the cool air, preferably, for being in~~ <sup>extend in a direction that is substantially</sup> perpendicular to the flowing direction of the cool air, thereby separating the cool air, <sup>into multiple flows</sup> and simultaneously, <sup>decreasing</sup> the circulation speed of the cool air. Preferably, the separators 100 are formed of flat members. Although not shown, the separators 100 ~~of the flat members~~ are respectively fixed to the inner surfaces of the ducts 50 and 60. Preferably, as shown in FIG. 2 and FIG. 3, the ducts 50 and 60 <sup>adjacent the openings</sup> are expanded toward the <sup>portion of the</sup> inside of the freezing chamber 30 and the refrigerating chamber 40 so as to provide the <sup>have a diameter that is greater than the diameter of the openings.</sup>

~~cool air to the innermost of the freezing chamber 30 and the refrigerating chamber 40.~~

Also, the openings 51, 52, 61 are provided to the ends of the ducts 50, 60. Accordingly, the additional characteristics related to the separators 100 are very advantageous to the uniform diffusion of the cool air inside the freezing chamber 30 and the refrigerating chamber 40.

Furthermore, <sup>B</sup> before discharging the cool air, the cool air collides with the separators 100, thereby forming a <sup>turbulent</sup> chaos flow of unsteady state. At this time, the <sup>turbulent</sup> chaos flow generated <sup>tends to</sup> several vortexes around the separators 100. <sup>is generated</sup> ~~In more detail,~~ an adverse pressure gradient <sup>generates</sup> in a flow boundary layer formed on the surface of the separators 100, so that

10 the separated <sup>flows</sup> passages of the cool air cause the separation at both ends of the separators

100. The separation generates at least two vortexes A between the separators 100 and the openings 51, 52, 61, <sup>so that</sup> the vortexes A flow <sup>in</sup> to opposite directions <sup>from the</sup> at respective both

ends of the separators 100. <sup>Each</sup> The vortex A has a specific frequency dependent on a shape and a dimension of the separator 100, and also has an intensity and a size <sup>that are</sup> being different

15 from each other, and <sup>that vary</sup> being varied continually. The discharged flow is excited by the vortexes between the separator 100 and the opening 51, 52, 61, <sup>and is progressing toward</sup>

~~the inside of the freezing chamber 30 and the refrigerating chamber 40 by oscillating or swing.~~ Accordingly, the cool air is uniformly diffused <sup>into</sup> to the freezing chamber 30 and the refrigerating chamber 40.

As a result, the flow of cool air into the refrigerating/freezing chamber tends to oscillate and move, and the

Also, as shown in FIG. 4, <sup>insertion of the separator 100 in the duct forms</sup> the two passages ~~are formed~~ between the separator 100 and the opening 51, 52, 61 ~~by the separator 100~~. That is, <sup>T</sup> the two passages are substantially opposite to each other, <sup>and</sup> whereby the separated cool air flows along the two passages. The passages substantially function as nozzles <sup>that form</sup> for ~~partially forming the two passages as two~~ jets B. <sup>contributing to the</sup> According <sup>↑</sup> as the two jets B collide with each other ~~in opposite or at a~~ predetermined angle, a surrounding static pressure rises above an atmospheric pressure, <sup>turbulent flow</sup> thereby ~~forming the flow of unsteady state~~. That is, this collision strengthens the vortex A generated by the separation of the cool air. Thus, the cool air oscillates greatly, so that the cool air is uniformly diffused and provided to the freezing chamber and the

10 refrigerating chamber.

Also, as a time the excited cool air stays in the ducts 50, 60 becomes long, the oscillation of the cool air is lost due to the resistance on flow. That is, <sup>T</sup> to obtain the maximum efficiency on diffusion of the flow, it is necessary to directly discharge the cool air <sup>excitation from</sup> maximally ~~excited by~~ the vortexes A. Accordingly, the openings 51, 52, 61 are

15 positioned adjacent to points of ~~generating~~ inference between the two vortexes A. Substantially, <sup>into the refrigerating/freezing chamber at the location of</sup> ~~T~~ the cool air ~~is excited maximally~~ at the point of the separated passages, <sup>experiences its maximum excitement</sup> that is, the point of ~~meeting~~ the jets B. In this respect, it is preferable to position the openings 51, 52, 61 <sup>meet</sup> for being adjacent to the point <sup>where</sup> of ~~meeting~~ the jets B. In due <sup>meet</sup> consideration of the aforementioned explanation, if an interval H1 between the separator

20 100 and the opening 51, 52, 61 is larger than a width of the opening 51, 52, 61, the flow

On the other hand, when  
 resistance to the excited cool air <sup>increases</sup> generates substantially. Preferably, the interval H1 is the same (or less than) <sup>as</sup> the width D2 of the opening 51, 52, and 61. ~~In the meantime,~~  
~~in case of that~~ the interval H1 is too small, it is hard to form and grow the vortexes A.

Thus, preferably, the interval H1 is 0.5 times of the width D2 of the opening 51, 52, and 61. Also, <sup>in ing</sup> ~~on formation~~ of the passage for the jets B and the vortexes A, it is useful to form the separator 100 in correspondence with the width D2 of the opening 51, 52, and 61. <sup>at least</sup>

With the ~~separators 100~~, <sup>separators 100 with respect to the</sup> an orientation of the openings 51, 52, 61 is also very important for the uniform diffusion of the cool air, and this will be described with reference to FIG.

5A to FIG. 6B.

FIG. 5A and FIG. 5B are schematic views of a cool air-supplying device according to the first embodiment of the present invention. FIG. 6A and FIG. 6B are schematic views of a modified cool air-supplying device according to the first embodiment of the present invention. The cool air-supplying device will be described with the reference to FIG. 5A to FIG. 6B, which will be explained in comparison with FIG. 1 to FIG. 3.

First, as shown in FIG. 5A and FIG. 5B, the cool air-supplying device has openings for discharging the generated cool air <sup>in</sup> at different directions. In more detail, the openings are comprised of first inlets 111 provided at a top wall of the freezing chamber 30 and the refrigerating chamber 40, and second inlets 112 provided at a sidewall of the freezing chamber 30 and the refrigerating chamber 40.

At this time, the first inlets 111 discharge the cool air toward the lower portion of the freezing chamber 30 and the refrigerating chamber 40. Also, the second inlets 112 discharge the cool air toward the upper portion of the opposite sidewall. Accordingly, the oscillated cool air is discharged from ~~the~~ different portions of the freezing chamber 30 and the refrigerating chamber 40 through the first and second inlets 111 and 112. That is, <sup>which</sup> a substantial range of discharging the cool air becomes wide, ~~so that it~~ is advantageous to the uniform diffusion of the cool air in the freezing chamber 30 and the refrigerating chamber 40. To obtain the same result, the first and second inlets 111 and 112 may be positioned as shown in FIG. 5B. Especially, ~~the~~ the first inlet 111 discharges ~~the~~ cool air <sup>substantially</sup> perpendicular to the cool air discharged from the second inlet 112.

~~As strengthening the inference and mixture in the cool air, a turbulent intensity of the cool air heightens.~~ Because the cool air flows from the inlets in perpendicular, crossing <sup>this also helps to</sup> directions, the flows intersect which increase the turbulence of the over flow. Thus, the oscillated cool air is uniformly diffused in the freezing chamber 30 and the refrigerating chamber 40. Simultaneously, ~~it is possible to~~ obtain a uniform temperature distribution. Also, the cool air-supplying device has outlets 120 for <sup>from</sup> discharging the cool air ~~of~~ the freezing chamber 30 and the refrigerating chamber 40 ~~to~~ the external. The outlets 120 are provided at lower sides of the freezing chamber 30 and the refrigerating chamber 40, so that the cool air <sup>introduced through</sup> ~~discharged from~~ the inlets 111 and 112 is not <sup>immediately</sup> ~~directly~~ discharged ~~to the external~~. Preferably, the outlets 120 are provided on both lower sidewalls of the freezing chamber 30 and the refrigerating chamber 40, to discharge the cool air rapidly.

back to the  
cool air generating  
device.

In connection with the freezing chamber 30, the second supplying part shown in FIG. 1 to FIG. 3 has only the third opening 61 corresponding to the second inlet 112. Referring to FIG. 1 to FIG. 3, in connection with the refrigerating chamber 40, the first supplying part has both the first and second openings 51 and 52 corresponding to the first and second inlets 111 and 112. Thus, in the refrigerator of FIG. 1 to FIG. 3, preferably, the second supplying part for the freezing chamber 30 has the additional opening corresponding to the first inlet 111. Also, in the freezing chamber 30, the outlet 120 corresponds to the fourth opening 62. In the refrigerating chamber 40, the outlet 120 corresponds to the second middle opening 22.

10 Preferably, as shown in FIG. 6A, the cool air-supplying device further includes third and fourth inlets 113 and 114, wherein the third and fourth inlets 113 and 114 function as openings. In this case, the third inlet 113 is provided at a lower portion in a sidewall of the freezing chamber 30 and the refrigerating chamber 40, below the second inlet 112. Thus, the third inlet 113 discharges the cool air toward a lower portion of an opposite  
15 sidewall. The fourth inlet 114 is provided on a bottom wall of the freezing chamber 30 and the refrigerating chamber 40, for discharging the cool air toward an upper portion of the freezing chamber 30 and the refrigerating chamber 40.

In the same way as the first and second inlets 111 and 112, the third inlet 113 discharges the cool air for being in-perpendicular to the cool air discharged from the fourth inlet 114.

20 ~~By the additional third and fourth inlets 113 and 114, a substantial range of discharging~~

└ further increase the turbulent flow in the chambers, and provide for a more uniform distribution of the cool air.

~~the cool air becomes wide, so that a turbulent intensity of the cool air heightens. Also,~~  
 the third and fourth inlets 113 and 114 generates a large turbulent flow in the center of  
 the freezing chamber 30 and the refrigerating chamber 40, and also generates the same  
 turbulent flow in the upper portion and the lower portion of the freezing chamber 30 and  
 the refrigerating chamber 40. Accordingly, the oscillated cool air is uniformly diffused  
 in the freezing chamber 30 and the refrigerating chamber 40.

*which has essentially*  
 The third and fourth inlets 113 and 114 may be provided as shown in FIG. 6B, ~~under the~~  
~~conditions of having~~ *as the arrangement shown in Fig. 6A.* In relation to the refrigerator of FIG. 1 to FIG. 3,

the first supplying part and the second supplying part respectively have the openings 51

and 61 corresponding to the third inlets 113. Accordingly, it is preferable for the first  
 supplying part and the second supplying part to have the additional openings  
 corresponding to the fourth inlets 114. Also, preferably, the outlet 120 <sup>③</sup> *are* is provided on the

center of the sidewall <sup>⑤</sup> of the freezing chamber 30 and the refrigerating chamber 40, ~~not to~~  
~~directly discharge the cool air from the inlets 111, 112, 113, and 114 to the external.~~  
*This prevents cool air introduced through*

Eventually, as the openings are provided as shown in FIG. 5A to FIG. 6B, the discharged  
 cool air generates the secondarily turbulent flow in the freezing chamber 30 and the  
 refrigerating chamber 40, thereby giving the more uniform diffusion of the cool air.

~~In the meantime, since~~ *In prior art refrigerators*  
~~the evaporator 71 is wide, the cool air discharged from the fourth~~  
~~opening 62 is concentrated on the center of the evaporator 71. Accordingly, the heat-~~  
~~exchange efficiency of the evaporator 71 is lowered. Also, the heat exchange is not~~  
*Because* *tends to be relatively*  
*directed forwards*

exchange efficiency of the evaporator 71 is lowered. Also, ~~the heat exchange is not~~  
*became little or no*

generated <sup>occurs</sup> at the left and right sides of the evaporator 71, ~~so that~~ frost <sup>be</sup> may generated at the left and right sides of the evaporator 71, thereby lowering the heat-exchange efficiency. ~~Thus~~, as shown in FIG. 7 to FIG. 9B, <sup>a</sup> ~~the~~ separator <sup>is</sup> 100 are provided in the fourth opening 62 for discharging the cool air circulated in the freezing chamber 30 and the refrigerating chamber 40 to the evaporator 71.

The separators 100 described in FIG. 8 have the same characteristics as the separators 100 of the first embodiment of the present invention explained with reference to FIG. 4.

That is, the separator 100 separates the cool air into at least two <sup>flows</sup> ~~passages~~ before discharging the cool air, thereby decreasing the flow speed of the cool air. By the

10 separation of the cool air, it is possible to form at least two vortices A between the

separator 100 and the opening 62. Also, two jets B are formed by the passage, ~~wherein~~ and

the two jets B collide with each other, <sup>to increase the turbulence of the flow.</sup> ~~for strengthening the vortices A.~~ Thus, the cool

~~air being oscillated~~ <sup>exiting the opening 62</sup> is uniformly diffused to the entire evaporator 71.

Also, the opening 62 is provided adjacent to the crossing point of ~~meeting~~ the two jets B,

15 so as to prevent the excited cool air from being lost. <sup>for this</sup> ~~In the same~~ reason, an interval H1

between the separator 100 and the opening 62 is same as (or smaller than) a width D2 of

the opening 62. Preferably, the interval H1 is 0.5 times of the width D2 of the opening

62. For <sup>ideal</sup> formation of the vortex A and the jet B, a width of the separator 100 is same as

the width D2 of the opening 62.

To smoothly guide the ~~oscillated~~ cool air to the evaporator 71, preferably, as shown in

FIG. 9A and FIG. 9B, the second supplying part may include an additional auxiliary duct

80. The auxiliary duct 80 is in communication with the fourth opening <sup>62</sup>~~80~~, and is  
~~extended for being~~ <sup>so that it is</sup> adjacent to the evaporator 71. Furthermore, the auxiliary duct 80

5 includes an auxiliary opening 81 oriented toward the evaporator 71, and the separator  
100 is provided adjacent to the auxiliary opening 81. Thus, as the cool air passes through  
the freezing chamber 30 and the refrigerating chamber 40, the cool air is oscillated by the  
separator 100, and is directly discharged to the evaporator 71. As a result, the cool air is  
uniformly diffused <sup>over</sup> ~~in~~ the entire evaporator 71.

10 In both the aforementioned first and second embodiments of the present invention, it is  
possible to improve the efficiency of the separator 100 by modification, which will be  
explained with reference to FIG. 10A to FIG. 12B.

First, as shown in FIG. 10A, preferably, the first <sup>and</sup> ~~and~~ second auxiliary ducts 50, 60, 80  
are partially expanded at the portions adjacent to the separators 100. That is, the  
15 expanded portions 50a, 60a, 80a substantially enlarge the circumferential space adjacent  
to the separators 100, <sup>which causes</sup> ~~whereby~~ the flow speed of the cool air <sup>to</sup> ~~is decreased~~ in the expanded  
portions 50a, 60a, 80a. Thus, the separators 100 decrease the loss on flow resistance, and  
simultaneously, separate the cool air.

Preferably, the width D3 of the expanded portions 50a, 60a, and 80a is 2 to 2.5 times ~~of~~  
20 the width D0 of the ducts 50, 60, and 80. The height H2 of the expanded portions 50a,

60a, and 80a is 1 to 1.2 times of the width D0 of the ducts 50, 60, and 80. Also, as <sup>shown</sup> ~~explained~~ in FIG. 4 and FIG. 8, the width D of the separator 100 is equivalent to (or smaller than) the width D0 of the ducts 50, 60, and 80, and the width D2 of the first to fourth openings and the auxiliary openings 51, 52, 61, 62, and 81. Also, the interval H1 is equivalent to (or smaller than) the width D2 of the openings 51, 52, 61, 62, and 81. Preferably, the interval H1 is 0.5 times of the width D2 of the openings 51, 52, 61, 62, and 81.

If the ducts 50, 60, and 80 <sup>expand</sup> ~~extend~~ rapidly and largely, the cool air momentarily has large resistance and great loss. Accordingly, as shown in FIG. 10B, the expanded portions 50a, 60a, and 80a have the structure of gradually expanding the ducts 50, 60, and 80. That is, the sidewalls of the expanded portions 50a, 60a, and 80a are inclined at a predetermined <sup>relative</sup> angle to the sidewalls of the ducts 50, 60, and 80. Thus, the expanded portions 50a, 60a, and 80a substantially decrease <sup>(5)</sup> the energy loss generated by the flow resistance. <sup>shape of the</sup>

<sup>If</sup> ~~in case~~ the separator 100 is formed of a flat member, the flow resistance is great, <sup>on the</sup> ~~which~~ <sup>an energy</sup> ~~cool air, thereby generating the loss in flowing the air, (that is, energy loss).~~ As described above, a drag coefficient of the flat member is 2.0. <sup>To reduce this energy loss, it is preferable to</sup> ~~Accordingly, there is requirement for~~ selecting a flowing separator 100 having a smaller drag coefficient, ~~for obtaining the separation of the passage and the decrease of the flowing speed in state of decreasing the loss in the cool air.~~

First, as shown in FIG. 11A, the separator 100 may be formed in a curved shape. Also, <sup>curved ends of the</sup> the separator 100 <sup>is protruded in opposite to</sup> <sup>in the same direction as</sup> the flowing direction of the cool air. In this case, the drag coefficient of the separator 100 is about 1.40. Also, as shown in FIG. 11B,

the separator 100 may be formed in an angularly bent shape, wherein the separator 100 <sup>extend</sup> <sup>ends of the</sup> may be ~~protruded in opposite to~~ the flowing direction of the cool air. The separator 100 <sup>in the same direction as</sup> has a drag coefficient of about 1.20.

Alternatively, as shown in FIG. 11C, the separator 100 may be formed in an oval shape, <sup>where</sup> <sup>are</sup> <sup>ed</sup> to have both sides being round ~~for the forward and opposite directions of the cool air.~~

The oval-shaped separator 100 has a drag coefficient <sup>which varies, depending on the characteristics</sup> being varied on the circumferential <sup>flow</sup> <sup>whirls</sup>

10 flow boundary layer. More specifically, ~~in case of forming a laminar boundary layer, the~~ <sup>when the separator forms</sup> drag coefficient is smaller than a coefficient of the separator of FIG. 11B and FIG. 11C.

~~In case of forming a turbulent boundary layer, the drag coefficient is much smaller. Also,~~ <sup>when the separator forms</sup> a plurality of protrusions or dimples may be formed on the surface of the separator

according to other modifications of the present invention. The protrusions or dimples  
15 induce the formation of the turbulent boundary layer around the separator 100, thereby decreasing the drag coefficient.

Meanwhile, the oscillation direction of the ~~discharged~~ cool air is ~~regarded~~ as the condition for improving the efficiency of the separator 100.

As shown in FIG. 12A and FIG. 12B, in the aforementioned first and second  
20 embodiments of the present invention, the plurality of openings 51, 52, 61, 62, and 81 are

formed in each of the corresponding ducts 50, 60, and 80. In this case, the openings 51, 52, 61, 62, and 81 are provided adjacent to one another, and the ducts 50, 60 and 80 are connected with the openings. As shown in the drawings, one duct may be connected with <sup>a</sup>the plurality of openings 51, 52, 61, 62, and 81 <sup>that are</sup>being adjacent to one another.

- 5 Alternatively, <sup>a</sup>the plurality of ducts may be respectively connected with ~~the plurality~~ of openings. The plurality of separators 100 are respectively provided to the openings 51, 52, 61, 62, and 81. In this state, the openings 51, 52, 61, 62, and 81 have the alternately changed sizes, and the respective separators 100 also have the sizes equivalent to the corresponding openings 51, 52, 61, 62, and 81.

- 10 Also, pairs of first supports 100a and pairs of second supports 100b are alternately extended from the opposite sides of the separators 100 to the <sup>edges of the</sup>openings 51, 52, 61, 62, and 81, to support the separators 100. Especially, ~~the pairs of the opposite sides of the openings supported by the first supports 100a are different from the pairs of the opposite sides of the openings supported by the second supports 100b.~~ <sup>orientation of the</sup> ~~orientation of the~~ <sup>is</sup> ~~orientation of the~~ In more detail, as shown in

- 15 the drawings, the first supports 100a support the left and right sides of the separators 100. Meanwhile, the second supports 100b support the lower and upper sides of the separators 100. According to this arrangement of the first and second supports 100a and 100b, the adjacent separators 100 separate the discharged cool air <sup>in</sup>by ~~the~~ different directions. That is, the separators 100 separate the cool air <sup>into</sup>by the lower and upper directions with the first

<sup>into</sup> <sup>flow</sup>

supports 100a, and separate the cool air <sup>into</sup> ~~by the~~ left and right <sup>flow</sup> directions with the second supports 100b.

~~After that,~~ <sup>↑</sup> vortexes are generated at the lower and upper sides of the separators 100 by the first supports 100a, and then the cool air is oscillated up and down, and is discharged  
 5 through the openings 51, 52, 61, 62, and 81. Also, vortexes are generated at the left and right sides of the separators 100 by the second supports 100b, and then the cool air is oscillated to the left and right sides, and is discharged through the openings.

Accordingly, the turbulent intensity of the flowing air firstly heightens in the ducts 50, 60, and 80, so that the oscillation of the cool air becomes greater. Also, the separators 100  
 10 oscillate the cool air <sup>in</sup> ~~at the~~ different directions, for example, at ~~the~~ perpendicular direction. <sup>⑤</sup> Thus, after the adjacent passages of the flowing air are discharged, the adjacent passages of the flowing air instantly interfere and mix with one another, thereby forming <sup>a</sup> ~~the~~ severe turbulent flow. As a result, the discharged cool air is uniformly diffused in the freezing chamber and the refrigerating chamber.

15

### ~~Industrial Applicability~~

As mentioned above, <sup>a</sup> ~~the~~ refrigerator according to the present invention has <sup>very many</sup> ~~the following~~ advantages. <sup>↑</sup>

<sup>↑</sup> In ~~the~~ <sub>the</sub> refrigerator according to the present invention, the separators oscillate the  
 20 discharged cool air, so that the discharged cool air is uniformly ~~and entirely~~ diffused in

the freezing chamber, the refrigerating chamber, and <sup>at the</sup> ~~the~~ evaporator. Accordingly, it is possible to perform the heat exchange in the refrigerating/freezing chambers in a short <sup>period of</sup> time, thereby improving the efficiency in the refrigerator.

It will be apparent to those skilled in the art that various modifications and variations can  
5 be made in the present invention without departing from the spirit or scope of the invention. Thus, it is intended that the present invention cover the modifications and variations of this invention provided they come within the scope of the appended claims and their equivalents.

ABSTRACT

A refrigerator is disclosed, which includes a body, <sup>having a main</sup> a refrigerating chamber and a freezing chamber provided <sup>storing</sup> in the body, for <sup>taking storage of foods</sup> a cool air-generating device provided in the body <sup>for generating</sup> a cool air, <sup>and</sup> a cool air-supplying device including at least one opening for discharging the cool air, <sup>and for circulating</sup> the cool air through the freezing chamber, the refrigerating chamber, and the cool air-generating device, <sup>and a</sup> separator provided adjacent to the opening <sup>for</sup> uniformly diffusing the cool air in the freezing chamber and the refrigerating chamber, <sup>by separating</sup> the cool air into at least two passages. <sup>flows</sup>

The separator acts to separate that are then brought back together. The collision and mixing of the two flows create a ~~turb~~ turbulent flow of air that is directed into the refrigerating and freezing chambers.
